(54) Title: HONEY BASED WOUND DRESSING

WO 01/41776 A2

(57) Abstract: The present invention is directed to the use of honey in medical dressings. Preferred embodiments modify honey with a viscosity increasing agent, resulting in a range of possible compositions including ointments and salves, self-adhesive gels such as for use on mouth ulcers and pustules, and pliable or flexible sheets which can be used as a wound covering. Preferred viscosity increasing agents include both particulate and continuous gels, respective examples of each including agars and alginates. Selected honeys preferably, but not necessarily, exhibit antibacterial properties other than what is merely conferred by osmolarity and sugar concentration effects.

HONEY BASED WOUND DRESSING

TECHNICAL FIELD

The present invention is directed to the use of honey in medical dressings. Preferred embodiments modify honey with a viscosity increasing agent, resulting in a range of possible compositions including ointments and salves, self-adhesive gels such as for use on mouth ulcers and pustules, and pliable or flexible sheets which can be used as a wound covering.

Alternatively the invention may be viewed as an improvement on prior art "moist wound dressings" by incorporating honey in the gel to potentially confer to such dressings antibacterial properties, anti-inflammatory properties, debriding qualities, and promotion of growth of wound tissue.

BACKGROUND ART

The use of honey in treating wounds have been long known, with such use being recorded in 4,000 year old Sumerian clay tablets. There are continuing records of its use throughout history, with an increasing number of medical reports near the beginning of this century. Recently the anti-bacterial properties of honey and its potential use as a wound dressing has attracted greater attention.

Recent international medical literature record honey as being effective as a dressing for wounds, burns and skin ulcers. Recorded observations include that inflammation, swelling and pain are quickly reduced, that sloughing of necrotic tissue occurs without the need for debridement, and that growth of tissues to repair the wound is stimulated. As a consequence, healing occurs rapidly with minimal scarring, and often without any necessity for skin grafting.

Work by the inventor and others has helped to establish that the effectiveness has been due primarily to anti-microbial properties of honey. Healing processes will not usually occur unless infection is cleared from a lesion, and investigations involving swabbing wounds dressed with honey has shown that infecting bacteria are rapidly cleared.

In this respect honey appears superior to the expensive modern hydrocolloid wound dressings which are favoured in the art as a moist dressing. Although tissue re-growth in the healing process is enhanced by a moist environment, and deformity is reduced if the re-growth is not forced down by a dry scab forming on the surface, moist conditions also favour the growth of infecting bacteria. The difficulty facing the prior art is that antibiotics are ineffective in this situation while antiseptics cause tissue damage and thus

slow the healing process. In contrast, honey causes no tissue damage and appears to actually promote the healing process.

While there is a need for moist dressings within the art, investigations involving honey as wound dressings have focussed primarily on unmodified honeys. As mentioned above,

5 dressing wounds with honey has been the most prevalent form of investigation, essentially attempting to maintain raw honey in contact with a wound as part of a moist dressing. However, while such methods may be useful for investigative trials, the techniques can be relatively time consuming to apply and maintain, and may be impractical in a number of situations.

10 A primary cause of this is the relatively fluid nature of most honeys – i.e. honey is runny at body temperature. Due to this fluidity, especially at body temperature, localising honey to the desired area may be difficult. Difficulties may be less for an incapacitated person in a hospital bed, though these difficulties generally preclude its use as a simple wound dressing on an active person.

15 Containment of unmodified honey is thus a problem, and no simple practical solution has been proposed. The soaking of absorbent materials, such as gauzes, in a dressing to be applied over a wound and then held in place by a further covering is a possibility though tends to be messy and would be difficult to apply except in a clinical situation. Even then applying such a dressing can be relatively time consuming and require the use of an 20 excessive number of relatively expensive sterilised coverings.

Another problem is that many wounds exude moisture and this causes the problem of further dilution of the honey exacerbating containment problems, especially where there is pressure on the dressing causing the diluted honey to be squeezed out. This dilution of the honey may also introduce other considerations such as a potential reduction in anti-bacterial activity due to dilution.

Accordingly, while the anti-bacterial properties of honey have been acknowledged, there are a number of practical problems to be overcome before honey can find widespread use as a practical dressing for wounds and other medical uses.

30 Similarly there are a number of problems associated with prior art 'moist' wound dressings, such as of the alginate type. The moist environment provided by these types of dressings favours the growth of micro-organisms and accordingly they cannot be used on infected wounds, even though this may otherwise be the preferred choice of dressing. The use of many antibiotics have also failed to keep unwanted microbial growth in check when 'moist-type' dressings are used in certain situations of this type. Accordingly, 35 medicine cannot always make use of the full potential of moist prior-art dressing types.

Reference will be made throughout the specification to the anti-microbial properties of honey. It is acknowledged that this is known in the art and a number of publications survey these properties. It is anticipated that a skilled addressee of the art would be familiar with the teachings of these publications insofar that many honeys possess anti-
5 microbial properties, with some exhibiting more activity than others. Consequently, this document shall not seek to establish that certain honeys do possess anti-microbial properties, nor shall it seek to set out a specific list comparing the properties of all honeys which may or may not have been publicly documented. Again it will be relied upon that anti-microbial properties associated with honey have been established in the prior art. By
10 way of reference, some relevant documents which address this are given:

- Molan, P. C. (1992) The antibacterial activity of honey. 1. The nature of the antibacterial activity. *Bee World* 73 (1): 5-28.
- Molan, P. C. (1992) The antibacterial activity of honey. 2. Variation in the potency of the antibacterial activity. *Bee World* 73 (2): 59-76.
- 15 - Willix, D. J.; Molan, P. C.; Harfoot, C. J. (1992) A comparison of the sensitivity of wound-infecting species of bacteria to the antibacterial activity of manuka honey and other honey. *Journal of Applied Bacteriology* 73 : 388-394.
- Cooper, R. A.; Molan, P. C. (1999) The use of honey as an antiseptic in managing *Pseudomonas* infection. *Journal of Wound Care* 8 (4): 161-164.
- 20 - Cooper, R. A.; Molan, P. C.; Harding, K. G. (1999) Antibacterial activity of honey against strains of *Staphylococcus aureus* from infected wounds. *Journal of the Royal Society of Medicine* 92 : 283-285.

A number of publications describe the large amount of variation in potency of antibacterial activity between different honeys. The variation can be as much as one-
25 hundred-fold, and is due to varying levels of antibacterial factors in honey additional to the sugar content and acidity in which there is little variation.

A patent document of some interest is US 5,177,065 by Silvetti. This document references the manufacture of wound dressings incorporating high levels of mono-
30 saccharides. In this document, it is the osmotic properties of concentrated sugar solution which are ascribed as providing any bacteriostatic effect. Consequently the described invention of Silvetti, and claims, concentrate on film-like compositions based on individual mono-saccharides or mono-saccharide blends.

A very brief reference to honey is made in the prior art discussion of Silvetti, though only in terms of dismissing honey as a folk medicine which would appear to have no useful
35 anti-bacterial effect in a wound healing preparation, such as the subject of that

specification. Accordingly, while this document is of some interest, it teaches away from the use of honey in a wound covering form or composition, and instead teaches towards the use of predominantly monosaccharide solutions.

Accordingly, it is an object of the present invention to address the problems associated with the prior art, or at least to provide the public with a useful choice. It also appears from the prior art that the use of honey in a medicinal sense is useful though difficulties associated with its use prevent its full potential from being realised, and hence the present invention also seeks to address this.

Further aspects and advantages of the present invention will become apparent from the 10 ensuing description which is given by way of example only.

DISCLOSURE OF INVENTION

According to one aspect of the present invention there is provided a medical composition comprising the combination of one or more honeys with a viscosity increasing agent.

15 According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which at least 50% of the composition is honey.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the viscosity increasing agent is an alginate based material.

20 According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the viscosity increasing agent is a natural product based gelling agent.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the combination is such that the 25 resulting composition is in the form of a firm, non-running gel.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the viscosity of the gel composition is such that it is suitable for application as an ointment or salve.

30 According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the viscosity of the gel composition is such that it is suitable for extrusion to fill wound cavities.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the gel-formed composition is substantially non-running at body heat.

5 According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the gel-formed composition is substantially non-running at 45°C.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the gel-formed composition includes moisture absorbing, trapping, or removing agents suitable for removing exudate
10 from a wound such that the gel-formed composition remains substantially non-running for an extended period of time after application to a wound when compared to a similar composition in which the said water trapping, removing or absorbing agents are absent.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the combination of honey(s) and
15 viscosity increasing agent(s) is such that the resulting combination is in the form of a formable and/or pliable putty that can be readily moulded into shape.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a putty-like composition is suitable for use as a wound dressing or covering.

20 According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a putty-like composition will substantially retain its state until pressure or force is applied to it.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a putty-like composition is
25 substantially non-running – at up to 45°C.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a putty-like composition will slowly dissolve over time in bodily fluid.

30 According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a slowly dissolving putty-like composition is suitable for internal use.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which the combination of honey(s) and viscosity increasing agent(s) is in the form of a flexible sheet.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a sheet-like embodiment is suitable for use as a wound dressing or covering.

5 According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a sheet-like composition possesses any one or more of the following characteristics:

- the inclusion of water absorbing, trapping, or removing components to assist in the removal of free exudate;
- is substantially non-running at body temperature;
- 10 - will slowly dissolve in body fluids.

According to another aspect of the present invention there is provided a medical composition, substantially as described above, in which a composition of any of the foregoing forms will soften at body temperature, when compared to room or storage temperature, to allow it to conform to the configuration of the wound or surface to which

15 it is applied or positioned, but which form remains substantially non-running – at up to standard body temperature, and more preferably to 45°C.

According to a further aspect of the present invention there is provided a wound dressing comprising at least a layer of a sheet or putty-like medical composition substantially as described above.

20 According to a further aspect of the present invention there is provided a wound dressing comprising a sheet composed of multiple layers of some or all of the compositions substantially as described above.

According to a further aspect of the present invention there is provided a wound dressing comprising a sheet composed of multiple layers of one, some or all of the compositions
25 substantially as described above in addition to a fabric to provide additional cohesive strength.

According to yet a further aspect of the present invention there is provided a modified wound dressing comprising a medical composition substantially as described above, applied to cover at least an area on a backing portion. The backing portion may be an adhesive material that the area that extends beyond the medical composition serves to 30 adhere the dressing to the surface of the skin surrounding a wound.

According to another aspect of the present invention there is provided a wound dressing substantially as described in the preceding paragraph, in which the backing portion may comprise one or more layers of a suitable material.

According to another aspect of the present invention there is provided a wound dressing, substantially as described above, in which an area of an aforesaid composition overlies at least part of the backing portion.

According to another aspect of the present invention there is provided a wound dressing, substantially as described above, in which an area of the backing portion in which the medical composition is present, is defined by a number of smaller localised regions of the medical composition distributed within the larger area (in which the medical composition is present) on the backing portion.

According to yet a further aspect of the present invention there is provided a wound dressing or medical composition, substantially as described above, in which a honey present in same is chosen to have anti-microbial or bacteriostatic properties.

According to yet a further aspect of the present invention there is provided a wound dressing or medical composition, substantially as described above, in which a chosen honey includes a non-peroxide anti-microbial or bacteriostatic component.

15 According to yet a further aspect of the present invention there is provided a wound dressing or medical composition, substantially as described above, in which a selected honey has a water content of 17.1% or lower.

According to yet a further aspect of the present invention there is provided a wound dressing or medical composition, substantially as described above, in which a selected honey has A_w of 0.94 or less, and preferably 0.86 or less.

According to yet a further aspect of the present invention there is provided a wound dressing or medical composition, substantially as described above, which has been sterilised with respect to clostridial spores by irradiation.

25 The present invention is directed to compositions, and products based thereon. Uses of the invention include applications in both human and veterinary medicine.

Preferred embodiments of the invention include one or more honeys exhibiting bacteriostatic or anti-microbial properties. It has been previously indicated that these properties in many honeys are well known, though there are difficulties associated with the use of honey for medical type uses. This includes the relatively fluid nature of honey and difficulties in localising it to the required area of treatment. There are also other associated difficulties, such as problems with wound exudate, and infection difficulties associated with moist dressings, which the present invention also seeks to address as part of its solutions for addressing the first problem.

Preferred embodiments of the present invention combine one or more honeys (for simplicity of description only one honey will generally be referred to in a composition

described herein, though it should be remembered that this may be substituted by a blend of one or more honeys) in combination with a viscosity increasing agent. Typically the nature of this viscosity increasing agent is such that the fluidity of the resulting composition is increased to the point that the resulting composition is substantially non-running. By non-running is meant a composition which, if placed on an incline, will not flow down the incline. It is acceptable that the lower viscosity embodiments of the present invention may deform or bulge, but they should not break down and flow to any except the most minimal degree. For the purpose of defining the invention, such an inclination may be taken to be a slope of 45°.

10 Further, it is envisaged that some embodiments of the present invention may soften at more elevated temperatures. Accordingly, unless otherwise stated, non-running will generally be taken at a temperature of 20°C. In many instances also, it is desirable that the composition also remains non-running at body temperature – which will be taken to be 40°C as many patients may also be exhibiting an elevated temperature. More 15 preferably, compositions may be substantially non-running to 45°C or higher.

The present invention may take a number of different forms. The less viscous forms will comprise a relatively soft gel which may be used as an ointment or salve. A potentially realisable advantage of the soft gels is that under the mild pressure of applying a covering, they may be forced into a wound to make intimate contact with the presented 20 surface of the wound. While this represents one possible use of such embodiments, it is also envisaged that there are other uses for such gel-like embodiments, such as for extruding into wound cavities. Previously mentioned have been applications such as gels and salves for use on ulcers and pustules. Varying gels may also be used intermediate the surface to which a dressing is to be applied, and the dressing. Preferably the dressing is a 25 honey based dressing (such as the sheet type embodiments herein).

In some applications the gel may even be used to help retain or adhere the dressing in the desired location. For instance a honey based sheet embodiment typically possesses absorbent properties and can be employed to help increase the viscosity of a thin layer of gel with which it is in contact. Hence a small amount of a softer honey based gel can in 30 some arrangements be used as an adhesive for a dressing – particularly for ulcers etc. It is also envisaged that there are other variations and embodiments of this principle, within the scope of the present invention.

Such embodiments may be stored and dispensed in different ways. They may be contained in tubes and dispensed in the manner of normal salves and ointments. They 35 may also be contained in sealed capsules or packages which may be opened to allow the contents to be squeezed into the area of use. Other arrangements are also envisaged.

A further embodiment of the present invention is an embodiment which is perhaps best described as being putty-like. Such an embodiment may be moulded or plied into ~~shape~~ by finger pressure, and will substantially retain that shape even under soft-to ~~mild~~ pressure. This not only allows the thickness of the resulting composition, when used as a 5 wound dressing, to be varied, but also allows it to be moulded for use in particular ~~areas~~ and locations. For instance, one could readily envisage its use when shaped to cover a wound on the bridge of a nose. This may be of some use in the area of cosmetic surgery.

As can also be appreciated, putty-like embodiments can also be used to provide ~~some~~ support and protection to some types of wounds, which gels and sheet-like embodiments 10 (to be described later) may not be able to provide. Putty-like compositions of varying degrees of stiffness and pliability are envisaged within the scope of the present invention.

The third main category of embodiments according to the present invention are the sheet-like embodiments which comprise a formed sheet which can be laid over a wound. These 15 may be pre-formed into a variety of shapes and sizes, though it is also envisaged that they may be easily trimmed to shape.

Typically such embodiments will be flexible enabling them to accommodate ~~different~~ contours and major irregularities on the surface over which they are applied. The ~~degree~~ of flexibility and softness may also be varied and it is also envisaged that the ~~physical~~ characteristics may slowly change over time when used in a moist dressing – especially as 20 wound exudate, body warmth, and other parameters have effect on their composition.

The three main categories of physical forms in which medical compositions according to the present invention may generally fall into have been described above. Compositions from these general categories may also be used in the preparation of other products – for instance, such as a layer on a backing material in a wound dressing. This is not to say 25 the present invention cannot take other forms than described above, though for ease of description it is determined that the categorising of various embodiments into these ~~three~~ main groups is more convenient. This will assist in describing the various possible methods for their preparation and uses, which will be described later herein, and which preparations and uses may overlap between the various categories. There are no distinct 30 boundaries between the categories, just bands in which one merges into the next.

It is also envisaged that apart from being non-running, various embodiments of ~~the~~ present invention may possess other qualities. For instance, in some cases it is desirable for a medical composition according to the present invention to contact a wound or ~~other~~ surface as intimately as possible. Because there is often some surface irregularity, ~~sheet~~ 35 and putty-like embodiments of the present invention may not necessarily make ~~such~~ intimate contact, whereas the gel-like embodiments will generally be more suitable for this purpose. This either allows the options of ensuring there is a layer of a ~~gel~~

composition intermediate in an overlying layer of a sheet or putty-like embodiment, or alternatively looking at other methods of increasing the intimacy of contact.

One such latter method is to tailor the compositions such that while they may be relatively firm yet pliable at room temperature for handling and trimming, they 5 substantially soften at body temperature, or at a temperature not too far above body temperature. This softening should be sufficient to allow the overlying composition to slowly mould into or contour to the wound – a process which may occur over minutes through hours. It is also envisaged, that in such embodiments a relatively thin layer of the material may be placed over the wound, and some gentle localised heat applied to soften 10 the material and better conform with the surface to which it is applied. Ideally, for such elevated-temperature-softening embodiments, the temperature to which it needs to be heated should be in the range of 40° - 50°C, and preferably towards the lower end of this range.

15 As a further or alternative method of increasing contact intimacy, embodiments which soften or swell in the presence of moisture can also be considered. In such cases, these may react to wound exudate, or even to a fine spray of water applied to the wound prior to the application of the dressing or covering. As many embodiments of the present invention are based on gelling substances, the selection of appropriate gels, or the incorporation of the appropriate amounts of various gels, makes this feasible. It is also 20 envisaged that for this embodiment, as well as other embodiments, sheets comprising multiple layers of different formulations of compositions according to the present invention can be used. Hence a layer of water softening/swelling composition may be applied to a layer of a firmer composition. Analogous multi-layer technology may also be incorporated for the heat sensitive embodiments described above.

25 Other modifications which may be incorporated in various embodiments include means for reducing free moisture such as wound exudate. Such embodiments perform a partial mopping up action to ensure that the area under a dressing remains moist but not wet. Again this may involve the use of suitably selected gelling agents which can absorb a certain amount of moisture from the wound. Other components may also be added which 30 perform such activities. These may include water absorbing components, and water removing components (which may work by chemical reaction) etc.

35 Embodiments of the present invention will, in their simplest form, comprise a combination of honey with a suitable viscosity increasing agent. Typically this agent will comprise a substance which forms a gel.

Selection of a suitable agent will involve a number of considerations. Such considerations include the suitability for the medical or the intended use; stability over

time; compatibility with honey; and the ability to form a product having the desired physical properties – e.g. flexibility and strength etc. A number of other considerations may also be involved, and commonly these will at least be partially dictated by the requirements of the user and the intended purpose of a particular embodiment.

5 There are a number of suitable viscosity increasing agents available and, as previously indicated, preferred embodiments of the present invention will rely on gelling agents. A number of gelling agents are available including various gums and polysaccharides, alginates, and both synthetic and natural polymeric compounds. Such gelling agents are well known in the art, – in particular in the food and medical arenas – and will not be

10 discussed in any specific detail herein apart from some representative examples given later herein. Some useful prior art referencing the use of gelling agents in medical type applications include US 4,948,575, US 5,674,524, US 5,197,945, US 5,735,812, US 5,238,685, US 5,470,576, US 5,738,860, US 5,336,501 and US 5,482,932. There are undoubtedly a number of other patent specifications also referencing the use of various

15 gels and polymers for medical use and in particular for wound dressings. Reference is made to these documents as a background to various viscosity increasing agents which may find use with the present invention.

Preferred embodiments rely upon the alginate salts to form a product of the desired viscosity (e.g. gel, putty or pliable sheet etc.). The alginates appear to be especially

20 suitable for use with the present invention as the physical properties of the gel product appear to be relatively easily controlled. In addition, they have proven to be suitable for many medical type uses.

Typically the gelled alginates are combined with the honey and any other optional components. By alginate selection one can use an alginate which gels upon blending with

25 honey, and/or rely upon another observed property of some alginates which is to gel when a polyvalent cation is introduced. For this latter type the gel promoting agents – typically polyvalent cations – can be introduced to form a gel product of the desired consistency. Any moulding, extruding, or forming processes should also be performed at this time so that the firmer embodiments 'set' into the desired configuration. Machining (e.g. slicing)

30 into the final form – such as sheets cut from a block – can also be incorporated into any manufacturing process.

Alginates also have another potentially realisable advantage in that introduced cations, or cations already part of the selected alginate, can be of benefit in some situations. For instance, calcium containing alginates may be selected for embodiments used where there

35 is bleeding, as calcium can promote blood clotting. There are also a wide range of cations which can be present or introduced into the various alginates which can provide the user with some choice, though consideration would need to be given to any potentially cytotoxic ions, such as ammonium ions.

Other potentially useful gelling agents include the hydrocolloids and hydrogels. These components tend to absorb moisture to form a moist healing environment, though tends to absorb less fluid than the alginates. Consequently, it is envisaged that they would not be used for embodiments for heavily exuding wounds in which the alginates would tend to

5 offer better performance. However, it is envisaged that combinations of various viscosity increasing agents may be used in particular embodiments, particularly if each imparts a slightly different property which helps fulfil a particular specification required by the user. For instance the hydrocolloids or hydrogels may be incorporated into gelling beads to vary properties such as the amount of fluid absorbed from a wound, etc.

10 Other optional materials may be included into various embodiments of the present invention. Some of these have been addressed previously, though there are also others. These may include various active pharmaceuticals, particularly to address concerns which extend beyond the ability of honey to address, or which augments or supplements the performance of honey. Some examples include fungicides, additional anti-bacterial agents etc.

15

Other optionally included components include filling materials which can change the consistency and physical properties of an embodiment of the present invention. In particular, it is envisaged that the putties may include various solid particles to alter their physical properties. Even the physical properties of more solid embodiments, such as

20 sheets, may also be altered by the inclusion of particular fillers. These fillers may include various particulate or granular materials which may be substantially inert or show some activity. Some examples include calcium carbonate, zinc oxide, barium sulphate etc. Other fillers may include flexible or soft components, such as small beads. These may be of polymeric materials. Various filling agents widely used in the pharmaceutical

25 industry may be considered for use with the present invention.

Further, non-particulate materials, such as fibres, may also be included to alter the physical properties. The inclusion of randomly placed strands of alginate fibres, or even woven alginate fibre material, may be embedded or included in various embodiments. These, either in addition to or without other fillers, can also significantly alter the

30 physical characteristics of various forms of the present invention.

As an extension of this principle, it is desirable for some embodiments of the present invention to be attached to a suitable backing material. This backing material may perform a number of roles, including acting as an intermediate between the honey composition and further backing layers, as a protective covering over the honey

35 composition, or to further alter the physical properties of the honey composition. In particular it is envisaged that these arrangements will typically be used for the sheet-like embodiments of the present invention and may include a number of various manufacturing techniques including applying the un-gelled composition to the backing

material so that it bonds to same during gelling, or techniques for bonding the gelled honey composition to the backing material after the honey composition has substantially gelled or been formed. Variations and other manufacturing techniques are also possible.

As a further consideration in manufacturing, at least part of the anti-bacterial effect in
5 some honeys is due to the presence of an enzyme producing hydrogen peroxide. As for many enzymes this is temperature sensitive, and thus any manufacturing technique should avoid heating the honey to the extent that there is significant deactivation of the enzyme. In preliminary trials performed by the applicant, a maximum temperature of 60°C was sustainable for up to one hour without any substantial enzyme degradation. These factors
10 will influence any manufacturing technique.

BRIEF DESCRIPTION OF DRAWINGS

Further aspects of the present invention will become apparent from the following description which is given by way of example only and with reference to the accompanying drawings in which:

15 Figures 1 are perspective diagrammatic views of some possible embodiments of a dressing;
Figure 2 is a side view of a possible embodiment of a dressing, and
Figures 3 are side views of further possible embodiments of a dressing.

BEST MODES FOR CARRYING OUT THE INVENTION

20 Examples 1

This group of examples is based on the use of alginates as a gelling and viscosity increasing agent for honey.

As a general procedure, finely powdered sodium alginate (the use of other alkaline metal
25 alginates may also be considered) is blended with honey warmed to approximately 60°C. It is desirable that this temperature is not exceeded so as to avoid degradation of any hydrogen peroxide producing enzyme in the honey.

As the alginate slowly dissolves and absorbs water from the honey, a gel begins to form. Stirring should continue during this process so that as any yet unblended and ungelled alginate does not settle out.

30 At this point a number of optional procedures may be followed depending upon the nature of the final product. For instance:

Example 1a

For high viscosity products (e.g. sheets) the gel should be rolled into a sheet of the desired thickness as soon as it has gelled sufficiently to be able to handle the rolling procedure. The sheets should be maintained at a temperature high enough for hydration of the alginate to be completed and the full viscosity to be achieved for this particular product. By way of example this may be 60°C for approximately one hour, or for longer periods at lower temperatures. This may vary according to the nature of the selected honey, the properties of the alginate selected etc., and thus some minor trial experimentation may be required to achieve an embodiment having the precise characteristics required by the user.

Example 1b

As an alternative to Example 1a, a low viscosity product (e.g. a gel formulation or ~~some~~ putties) the blended mixture should be held at the elevated temperature to allow hydration of the alginate to be completed and the full viscosity achieved before it is packed ~~or~~ formed into the desired configuration. Some softer sheet-like embodiments may be ~~also~~ formed according to this method.

Example 1c

For intermediate products, such as the putties, optional fillers and additives altering ~~the~~ physical properties of the resulting product (e.g. fibres) are preferentially introduced ~~after~~ the alginate has been substantially homogeneously dispersed throughout the honey ~~and~~ while the gelling process is occurring. The inclusion of such additives may also occur ~~at~~ other times, though it is noted that their inclusion prior to alginate addition may interfere with the ready blending of the alginate with the honey in some instances, while addition at a later stage may be more difficult for some embodiments e.g. the addition of ~~fibres~~ after gelling has substantially occurred.

Example 2

Many alginates also exhibit gelling and cross linking properties promoted by the presence of polyvalent cations. These often tend to form tougher and less soluble alginate materials and thus may find use in a number of embodiments for altering physical characteristics of the resulting product. Typically it is envisaged that such modification will be used primarily for the sheet-like embodiments, particularly as a way of increasing the strength or solubility properties of the resulting sheet.

The polyvalent cations may be introduced in a number of ways, including the introduction of a soluble solution of polyvalent cations during the blending procedure. Preferably, ~~this~~ should be after gelling of the blend has initiated so as to avoid thickening reactions ~~which~~

interfere with the dispersion and hydrating of all of the sodium (or other) alginate being blended with the honey. However, as can be appreciated, adding polyvalent cations at different points can theoretically substantially alter the characteristics of the resulting product and thus a number of options remain open to the user to allow them to tailor the physical characteristics of various embodiments according to the intended end use and user requirements.

A range of polyvalent cations may be used, though toxicity considerations need to be given. It is anticipated that soluble calcium salts, such as calcium chloride, may be introduced at relatively low concentrations to promote the various gelling and cross linking reactions.

Example 3

This example is directed to the forming of a gel into sheets. This may be achieved by placing a gel such as from Examples 1a or 1b between sheets of a non-wettable material – on a lab scale this comprised plastic or wax paper – and rolling it to a uniform thickness.

As a variation, a gauze fabric or other suitable material may be placed on top of the lower non-wettable sheet prior to the pouring of the gel. The rolling procedure is completed with the result being a sheet-like gel bonded to the gauze. Figure 3a illustrates the result of such an embodiment, with the sheet of gelled honey (31) at least partially impregnating and bonding to the gauze or comparable material (33).

As a further variation, reinforcement may be provided in the centre of the gel. Here a layer of gel may be poured to cover the lower sheet, followed by placement of the gauze (or other reinforcing/backing material) followed by another layer of gel. The rolling procedure is then performed resulting in a sheet in which the gauze or fabric is embedded within the sheet. Figure 2a illustrates the result of such a method with the gauze (or other suitable material)(23) embedded within the gelled honey (21). As a further option this may be bonded to a further backing sheet (25). This can be achieved by pouring the lower first layer of gelled honey (21) onto this layer (25), prior to placing the gauze (23) and top gel layer.

As a variation of this technique, the gel may be formed into two thin sheets, with the gauze then sandwiched between the sheets of the gel (still at an elevated temperature) and the rolling process re-performed on the sandwiched layers.

Example 4

For a high viscosity product which is highly absorptive and suitable for use on heavily exuding wounds, the procedures described above are performed with 1 gram of sodium alginate with 5 ± 2.5 grams of honey.

Example 5

For a flexible product which is moderately adhesive and moderately absorptive and suitable for use on lightly exuding wounds, 1 gram of sodium alginate is combined with 10 ± 2.5 grams of honey.

5 Example 6

For a highly flexible and adhesive product suitable for use on dry wounds, 1 gram of sodium alginate is combined with 15 ± 2.5 grams of honey.

Example 7

10 For a lower viscosity product suitable for use as a gel (such as packed into a tube) to fill cavities and wounds, 1 gram of sodium alginate is combined with 17.5 grams or greater of honey, with the preferred amount being around 20 grams.

Example 8

15 For a putty-like product, to the combinations outlined in Examples 6 and 7 is included sufficient fine filler material to achieve the desired consistency. Preferred filling agents include finely powdered calcium carbonate. Despite the insolubility of this component, it may nevertheless have some effect on any gelling reaction should it be added while gelling is still occurring. Previous comments on polyvalent cations are referred to. The role of calcium in promoting blood clotting is also noted.

20 Other gelling agents, such as hydrogels, and various colloids, may be also included in these embodiments to vary the elasticity, pliability, and other physical characteristics of the putty. These may be in the form of blended components contributing to gelling, or even as firm components blended into the gel mixture as fillers.

25 These techniques may even be used in other embodiments. For instance, figure 3b illustrates the presence of fibrous strands (35) (e.g. alginate fibres) and particulate matter (37) dispersed in the gelled matrix (31).

Example 9

This example deals with the selection of honey for use with the present invention.

30 A large amount of this information is already referenced in the prior art identified earlier within this specification, and in particular publications by the inventor – Peter Molan. These publications reference the bacteriostatic and bactericidal effects of various honeys and thus reference may be made to this literature for identifying useful bactericidal honeys.

In addition, it is noted that while the osmolarity effect and peroxide effects of many honeys contribute to their anti-bacterial properties, research has also indicated that other components in some honeys also contribute to any bactericidal effects. It is considered, that for use in the present invention, these latter groups of honeys may be preferred, 5 particularly for dressing and embodiments which may be stored for an extended period of time, or used under conditions which may result in degradation of any peroxide forming enzyme in the honey.

As can be envisaged also, the limitation on the maximum temperature to which the honey is subjected during manufacturing (to avoid enzyme degradation) may be overly 10 restrictive for some embodiments. In such cases, honeys possessing bactericidal effects other than from the peroxide, may find use here as it appears that some of the active components would be less sensitive to temperature.

Some preferred honeys for use with the present invention include honeys derived from leptospermum species such as, for instance, manuka and jellybush. These honeys tend to 15 exhibit significant antibacterial properties arising from non-peroxide factors present, in addition to peroxide associated antimicrobial properties.

Additional honeys of interest include those derived from rewarewa (*Knightia excelsa*), kanuka (*Kunzea ericoides*), and from the honeydew present on beech (*Nothofagus solandri*).

20 Example 10

An alternative method for the manufacturing process, that involves less heating of the honey than would be required to gel honey containing a powdered form of the gelling agent dispersed in it, is to hydrate the gelling agent in hot water then mix this solution of the gelling agent with the honey and then dry the mixture by applying heat and/or a flow 25 of air to a film of the mixture. This alternative method for the manufacturing process is particularly useful for use with gelling agents which do not hydrate as readily as alginates, such as pectin or plant gums.

Example 11

A final consideration in any manufacturing process is the presence of contaminants in 30 honey. Being a natural product, there may be a variety of naturally occurring contaminants in the honey. This may include toxic substances from honeys sourced from particular flowers – ideally these honeys should be avoided unless there are some benefits for including such substances in a particular application. For instance, many toxic plants produce chemicals, such as digitalis, which have specific medical uses when used in 35 controlled amounts.

A more prevalent problem is the presence of microbial spores such as clostridial spores. However, it has been demonstrated that these may be eliminated by gamma-radiation of honey, without destruction of any of the antibacterial activity of honey, and thus irradiation techniques may be considered for various embodiments.

5 Example 12

On a large scale, the application of gelled honey to a backing substrate may differ substantially from that described herein. It is envisaged that one option is to 'print' or 'paint' the gelling composition on to the substrate prior to it fully setting. Hence areas can be printed or painted on to the appropriate areas of a substrate material, which can 10 then be trimmed into an appropriate size, such as for a dressing.

Figure 1a illustrates a dressing (11) which may have been produced by this method (but also by other techniques). Here an area (13) of gelled honey matrix has been applied centrally within a substrate (15).

Figure 1b is an enlargement showing that in these embodiments the layer of gelled 15 composition need not be continuous but may be made up of smaller regions (17). This may also allow a more open and breathable wound contact portion, which may be advantageous in some instance.

As can be appreciated also, various techniques described herein can be combined to produce more complex embodiments encompassing a number of different features.

20 Example 13

Uses of varying embodiments of the present invention are varied. It is envisaged that sheet like embodiments will be used in applications similar to those for which conventional dressings are used.

Gels and salves can be used in the manner of conventional gels and salves. They may be 25 applied directly into a wound cavity which represents an application for which many gels and salves possessing antibacterial properties may not be able to be used. Topical use inside the oral cavity for ulcers and abscesses of the mouth and gum diseases are another potential use of varying gel-like and other embodiments.

Gel-like embodiments may also be used as an intermediate between the substrate (e.g. 30 skin or wound etc.) and a dressing, preferably a honey-based dressing such as described herein. This can help eliminate any air spaces, and fill irregularities in the substrate surface that the dressing is unable to conform to.

Further, if it is in a drying environment, many gel like embodiments may increase in viscosity. A gel used between dry skin (such as may surround a wound) and an absorbent

dressing (such as a honey based sheet dressing described herein) can thicken over time as moisture migrates from it. In such a case the applied gel can act in the role of a ~~small~~ adhesive or bonding agent to help keep the dressing in place. This can be of use in a number of applications, including for instance around ulcers, boils, pustules, carbuncles,

5 acne and a variety of other 'dry' afflictions, as well as taking advantage of normal dry skin surrounding wounds and other injured areas.

Thicker, pliable and mouldable embodiments have a range of potential applications including applications where some support may be required in the wound area. Such embodiments may also find use in dental and oral applications, including temporary

10 fillings or covers for teeth and gums.

As can be appreciated, there is a wide potential range of applications for the varying embodiments of the present invention. It will be appreciated that many such uses ~~will~~ become apparent to the skilled reader and addressee of the art in light of the description given herein, and it should be recognised that the limited range of possible uses ~~and~~ examples given herein are by way of example only and do not represent the entire ~~range~~ of potential uses.

Example 14

The following data represents anecdotal trial results from use of varying embodiments ~~of~~ the present invention.

20 *Example 14a*

In a leg ulcer where exudation was severe, initial treatment consisted of alginate based dressing sold for heavily exudating wounds. After no observable progress was made ~~over~~ extended period of time, a wound dressing according to the present invention was trialled. This consisted of 5mm thick high alginic proportion (1 part alginate:5 part honey) pliable

25 sheet positioned over wound and bandaged over. Wound dressing was changed daily ~~and~~ new sheet applied. Exudate was absorbed satisfactorily by dressing. An observable result was significantly reduced exudation from wound within a few days. Wound became manageable, and problems associated with prior art alginate dressings ~~were~~ eliminated.

30 *Example 14b*

In a diabetic foot ulcer on foot underside, pliable sheet embodiment was used. Most ~~prior~~ art dressings were unsuitable for this location as squeezed out from weight on foot. ~~This~~ was not a heavily exudating wound though high alginic proportion (1:5) was used ~~to~~ provide firm sheet. Wound showed satisfactory healing despite known difficulty of

healing of diabetic foot ulcers, and failure of prior art products tried up until use of present invention, to result in any improvement or healing.

Example 14c

In a smashed jaw with eroding jaw bone from infection, there was no improvement over 5 18 month period using traditional techniques. Pain in patient was present and occasionally acute. In this case a pliable putty was used (1:5 ratio putty) and was fashioned to appropriate shape to cover wound. This dressing was replaced regularly at intervals of several hours (due to partial dissolving of putty by saliva). Wound healing progressed satisfactorily with rapid pain relief as added benefit.

10 *Example 14d*

An alternative embodiment using agar, which sets into a solid gel, may be used on skin grafts to immobilise the graft – this is in accordance with current practice of occasionally using a dressing to hold graft in place by surgeons. Typically a sheet type embodiment utilising 1-10% agar by weight. Sheet of gauze is embedded into 1mm thickness of gel 15 (around 1% agar). Preparation may be by heating dissolved agar solution first and then stirring heated agar solution into cold honey. This is then applied over gauze to embed. The result is soft pliable sheet, with tackiness. This can be overlaid over graft or wound etc., and tackiness helps grip skin and prevent sliding.

This embodiment utilises a particulate gel (e.g. agar where particles stick to each other in 20 a 3-d net) as opposed to a continuous gel (e.g. alginate) which tie up the water but where particles can roll over each other to give pliability and mouldable characteristics. Different embodiments may use one or other of these types of gelling agents. Can also blend different gel types to give products of intermediate characteristics.

Example 14e

25 One other appln is to use softer formulation (1:10 – 1:20 alginate type typically) on acne. Similar uses on boils etc. Such embodiments are more discreet than sticking plaster and may also be used for mouth ulcers. Acne embodiments may be in the form of a gel, ~~salve~~, or ointment, and may also include other components such as pigments (preferably ~~flesh~~ coloured) and/or sulphur.

30

Aspects of the present invention have been described by way of example only and it should be appreciated that modifications and additions may be made thereto without departing from the scope thereof.

THE CLAIMS DEFINING THE INVENTION ARE:

1. A medical composition comprising the combination of one or more honeys with a viscosity increasing agent.
2. A medical composition as claimed in claim 1 in which at least 50% (by weight) of the composition is honey.
3. A medical composition as claimed in claim 1 in which the viscosity increasing agent is an alginate based material.
4. A medical composition as claimed in claim 1 in which the viscosity increasing agent is a natural product based gelling agent.
5. A medical composition as claimed in claim 1 in which the combination is such that the resulting composition is in the form of a non-running gel.
6. A medical composition as claimed in claim 5 in which the viscosity of the gel composition is such that it is suitable for application as an ointment or salve.
7. A medical composition as claimed in claim 5 in which the viscosity of the gel composition is such that it is suitable for extrusion to fill wound cavities.
8. A medical composition as claimed in any one of claims 5 through 7 in which the gel composition is substantially non-running at body heat.
9. A medical composition as claimed in any one of claims 5 through 7 in which the gel-formed composition is substantially non-running at 45°C.
10. A medical composition as claimed in any one of claims 5 through 9 in which the gel-formed composition includes moisture absorbing, trapping, or removing agents suitable for removing exudate from a wound such that the gel-formed composition remains substantially non-running for an extended period of time after application to a wound when compared to a similar composition in which the said water trapping, removing or absorbing agents are absent.
11. A medical composition as claimed in claim 1 in which the combination of honey and viscosity increasing agent(s) is such that the resulting combination is in the form of a formable and/or pliable putty that can be readily moulded into shape.
12. A medical composition as claimed in claim 11 in the form of a putty-like composition suitable for use as a wound dressing or covering.

13. A medical composition as claimed in claim 11 in the form of a putty-like composition and which will substantially retain its state until pressure or force is applied to it.
14. A medical composition as claimed in claim 11 in the form of a putty-like composition and which is substantially non-running at up to 45°C.
15. A medical composition as claimed in claim 11 in the form of a putty-like composition which will slowly dissolve over time in bodily fluid.
16. A medical composition as claimed in claim 15 in the form of a slowly dissolving putty-like composition suitable for internal use.
17. A medical composition as claimed in any one of claims 11 through 16 which includes an alginate as a viscosity increasing agent.
18. A medical composition as claimed in any one of claims 11 through 16 which includes a gelling agent forming a continuous gel, as a viscosity increasing agent.
19. A medical composition as claimed in claim 1 in which the combination of honey(s) and viscosity increasing agent(s) is in the form of a flexible sheet.
20. A medical composition as claimed in claim 19 in which said sheet-like embodiment is suitable for use as a wound dressing or covering.
21. A medical composition as claimed in claim 19 which uses a gelling agent forming a continuous gel, as a viscosity increasing agent.
22. A medical composition as claimed in claim 21 in which the gelling agent is ~~an~~ alginate.
23. A medical composition as claimed in claim 19 which uses a gelling agent forming a particulate gel, as a viscosity increasing agent.
24. A medical composition as claimed in claim 23 in which the gelling agent is an agar or gelatine.
25. A medical composition as claimed in claim 19 which uses as viscosity increasing agents a combination of gelling agents, including at least one gelling agent which typically forms a continuous gel, and at least one gelling agent which typically forms a particulate gel.
26. A medical composition as claimed in any one of claims 19 through 25 in which said sheet-like composition possesses any one or more of the following characteristics:

- the inclusion of water absorbing, trapping, or removing components to assist in the removal of free exudate;
- is substantially non-running at body temperature;
- will slowly dissolve in body fluids.

27. A medical composition as claimed in any one of claims 19 through 25 which will soften at body temperature, when compared to room or storage temperature, to allow it to conform to the configuration of the wound or surface to which it is applied or positioned, but which form remains substantially non-running – at up to standard body temperature, and more preferably to 45°C.

28. A wound dressing consisting of at least one layer of a sheet-like medical composition as claimed in any one of claims 19 through 27.

29. A wound dressing as claimed in claim 28 which includes a reinforcing material.

30. A wound dressing as claimed in claim 29 in which the reinforcing material is selected from a group including: gauze, mesh, random fibres, and woven fabric.

31. A wound dressing as claimed in claim 29 or claim 30 in which the reinforcing material is embedded in the medical composition.

32. A modified wound dressing consisting of a wound dressing as claimed in any one of claims 28 through 31 applied to a backing material.

33. A modified wound dressing as claimed in claim 32 in which the backing material is a fabric.

34. A modified wound dressing as claimed in claim 32 in which the backing material includes adhesive areas other than in areas coextensive with the wound dressing, allowing the modified wound dressing to be applied and adhere to skin or other application surface.

35. A modified wound dressing consisting of a backing portion on which is present a wound patch including a medical composition as claimed in any one of claims 1 through 27, and in which an area of the backing portion in which the medical composition is present, is defined by a number of smaller localised regions of the medical composition distributed within the larger area (in which the medical composition is present) on the backing portion.

36. A medical composition consisting of honey in combination with a viscosity increasing agent, for use in the treatment of a pustule, the composition being substantially non-running at normal body temperature.

37. A medical composition consisting of honey in combination with a viscosity increasing agent, for use in dressing wounds, the composition being substantially non-running at normal body temperature.
38. A medical composition consisting of honey in combination with a viscosity increasing agent, for use in the treatment of ulcers, the composition being substantially non-running at normal body temperature.
39. A medical composition consisting of honey in combination with a viscosity increasing agent, for use in the treatment of burns, the composition being substantially non-running at normal body temperature.
40. A medical composition consisting of honey in combination with a viscosity increasing agent, for use in covering skin grafts, the composition being substantially non-running at normal body temperature.
41. The medical composition of claim 40 in which the viscosity increasing agent is agar.
42. The use of honey in combination with a viscosity increasing agent in the manufacture of a substantially non-running composition for use in addressing or treating any one of: acne, pustules, burns, recovery of skin grafts, ulcers, wounds, and including exudating wounds.
43. The use of honey in combination with a viscosity increasing agent in addressing or treating any one of: acne, pustules, burns, recovery of skin grafts, ulcers, wounds and including exudating wounds.
44. The use of a medical composition as claimed in any one of claims 1 through 27 in addressing or treating any one of: acne, pustules, burns, recovery of skin grafts, ulcers, wounds and including exudating wounds.
45. The use of a wound dressing as claimed in any one of claims 28 through 31 in addressing or treating any one of: acne, pustules, burns, recovery of skin grafts, ulcers, wounds and including exudating wounds.
46. The use of a modified wound dressing as claimed in any one of claims 32 through 35 in addressing or treating any one of: acne, pustules, burns, recovery of skin grafts, ulcers, wounds and including exudating wounds.
47. A medical composition in the form a salve, gel, or ointment, consisting of a honey in combination with a viscosity increasing agent, said composition also including at least one of: a pigment, and sulphur.

48. The composition of claim 47 which includes a pigment, said pigment being flesh coloured.
49. A medical composition as claimed in any one of claims 1 through 27 in which a honey present in same is chosen to have anti-microbial or bacteriostatic properties.
50. A medical composition as claimed in claim 49 in which a chosen honey includes a non-peroxide anti-microbial or bacteriostatic component.
51. A medical composition as claimed in claim 49 or claim 50 in which a selected honey has a water content of 17.1% or lower.
52. A medical composition as claimed in any one of claims 49 through 51 in which a selected honey has A_w of 0.94 or less.
53. A medical composition as claimed in any one of claims 49 through 51 in which a selected honey has A_w of 0.86 or less.
54. A medical composition as claimed in any one of claims 1 through 27, or 49 through 53 which has been sterilised with respect to clostridial spores by irradiation.
55. A wound dressing as claimed in any one of claims 28 through 35 in which a honey present in same is chosen to have anti-microbial or bacteriostatic properties.
56. A wound dressing as claimed in claim 55 in which a chosen honey includes a non-peroxide anti-microbial or bacteriostatic component.
57. A wound dressing as claimed in claim 55 or claim 56 in which a selected honey has a water content of 17.1% or lower.
58. A wound dressing as claimed in any one of claims 55 through 57 in which a selected honey has A_w of 0.94 or less.
59. A wound dressing as claimed in any one of claims 55 through 58 in which a selected honey has A_w of 0.86 or less.
60. A wound dressing as claimed in any one of claims 28 through 35, or 55 through 59 which has been sterilised with respect to clostridial spores by irradiation.
